

a) Pose estimation results of scenario 1 where the robot is allowed for free movements without restriction. The computed RMSE of the prediction to ground truth is 0.025483 m

b) Pose estimation results of scenario 2 where the robot movement is blocked by a box of rocks. The computed RMSE of the prediction to ground truth is 0.0395 m

b) Pose estimation results of scenario 3 where the robot position is manipulated by hand. In this scenario the motion capture failed in tracking the reflective markers hence no ground truth is available, however our pose estimation still outputs a relatively accurate result under such large deformation.
